Corn Response to Phosphorus Starter Fertilizer in North Dakota

Materials and Methods

Location and years: NDSU Carrington Research Extension Center; 2007-21.

Soil: Heimdal-Emrick and Fram-Wyard loams; 2.6% to 3.8% organic matter; 5.9 to 8.2 pH (primarily 7.5 or greater); 3 to 20 parts per million (ppm) P (Olsen test; most sites in the low to medium range at 8 ppm or less).

Standard treatments: 10-34-0 applied in a 2x0” band (2 inches horizontally placed from planted seed) with a single-disk coulter or in-furrow with seed (Photo 2). P application rates were based on NDSU corn fertilizer recommendation tables (Franzen, 2017).

The acres of corn planted in North Dakota for grain increased from about 1 million in 2000 to more than 4 million in 2021, and averaging 2.4 million per year since 2000. Field trials in North Dakota continue to evaluate starter fertilizer recommendations derived from other north-central U.S. land-grant universities.

NDSU recommends phosphorus (P) starter fertilizer be placed within 2 inches of the seed in-furrow (also called “pop-up”) or banded near the seed at planting time (Franzen, 2017). The P starter fertilizer provides the potential to increase early season plant growth by increasing nutrient uptake, and ultimately increase grain yield and test weight.

This publication summarizes results of NDSU P-based starter fertilizer trials conducted in east-central North Dakota that evaluated corn grain yield response, primarily with liquid ammonium phosphate (10-34-0) applied using different methods and rates.

uptake. No additional fertilizer P was applied to supplement P in the starter treatments. Best management practices, including providing adequate levels of plant nutrients besides P, were used for corn production.

Results and Discussion
In individual trials (site-years), corn grain yield response did not always occur among fertilizer treatments.

Averaged across eight site-years, band- and in-furrow-applied 10-34-0 increased yield 5 to 7 bushels per acre (4% to 5%), compared with the untreated check (Figure 1). Yield between the two starter fertilizer application methods was statistically similar.

![Figure 1. Corn grain yield between band and in-furrow application of 10-34-0, Carrington, 2008-16 (8 site-years).](image)

Plant stand was similar between band (30,100 plants per acre) and in-furrow (28,800 plants per acre), with 10-34-0 application rates ranging from 2.5 gallons per acre (gpa) up to 6 gpa. Averaged across five site-years with 10-34-0 rates of 5 to 6 gpa, the number of days from corn seed planting to plant emergence was similar among the check, 2x0” band and in-furrow application of fertilizer (data not shown).

Also, ear silks emerged slightly earlier (one to two days) with starter fertilizer application, compared with the check. Averaged across 11 site-years, grain harvest moisture was similar and test weight increased slightly with band applications of 10-34-0, compared with the check (Table 1).

![Figure 2. Corn grain yield between 10-34-0 application methods, Carrington, 2013-15 (3 site-years).](image)

The banded fertilizer rate was one-third less compared with the broadcast rate in the trials. The broadcast fertilizer was applied immediately after planting (PRE) without mechanical incorporation in 2013. The broadcast fertilizer was preplant applied and incorporated (PPI) in 2014-15.

Yield increased with 3 and 6 gpa of in-furrow-applied 10-34-0, compared with the check, averaged across six site-years (Figure 3); however, yield was similar between fertilizer rates.

![Figure 3. Corn grain yield between rates of in-furrow applied 10-34-0, Carrington, 2007-16 (6 site-years).](image)

Averaged across three site-years, yield statistically increased with band-applied 10-34-0 compared to the check, while broadcast-applied 10-34-0 had similar yield as the check (Figure 2). This supports the recommendation that banded P applications are more efficient in producing yield, compared with broadcast P applications for corn.

Soil P: 3-20 ppm (very low to very high). 10-34-0 application rate (gpa): 2.5-12.
Averaged across three site-years, yield did not improve with a split application of 10-34-0 using band plus in-furrow (IF) placement, compared with similar rates of only band or in-furrow application of fertilizer (Figure 4).

Soil P: 5-10 ppm (low to medium). 10-34-0 total application rate (gpa): 2010=6, 2012-13=12.

At similar rates of in-furrow-applied P, the three site-year yield average with low-salt fertilizer 6-24-6 was similar to 10-34-0 (Figure 5). Also, plant stands were similar between the two fertilizers (data not shown). Potassium (K) soil levels in the trials were high to very high.

Averaged across four site-years, yield was similar with soil surface application (near seed furrow) of 10-34-0 at planting compared with in-furrow application (Figure 6). Rainfall among the four years, ranged from 0.1 to 0.4 inches, three to five days following surface application of 10-34-0 (North Dakota Agricultural Weather Network). Rainfall is desirable to move the fertilizer below the soil surface to be accessed by the developing root system of corn seedlings.
Summary

- Corn grain yield was similar with band and in-furrow 10-34-0 application, and starter fertilizer increased yield, compared with the untreated check. Also, test weight increased slightly with band application of 10-34-0, compared with the check.

- Yield was similar between the 3- and 6-gpa rates of in-furrow-applied 10-34-0.

- Yield did not improve with a split application of 10-34-0 using band plus in-furrow placement, compared with similar rates of only band- or in-furrow-applied fertilizer.

- Deep-band (5 to 6 inches deep, fall or spring placed) or deep-band plus in-furrow-applied 10-34-0 had similar yield as the planting-time band-applied fertilizer.

- Yield was similar between in-furrow-applied 10-34-0 and the low-salt fertilizer 6-24-6.

- Yield was similar between in-furrow- and soil-surface-applied 10-34-0.
