

Pasture Management for Western North Dakota
Project No. 1906

**Complementary Rotation Grazing System in
Western North Dakota**

Llewellyn L. Manske, Thomas J. Conlon and James L. Nelson

Introduction:

Complementary grazing uses domesticated grass, legume or annual crop pastures to add to or complement native range pastures. Management of native range and domesticated grass pastures must be based on sound ecological principles that consider the growth and development of the dominant species and the physiological needs, weaknesses and strengths of the plants to maintain productive stands. The nutritional needs of the livestock must be included in management considerations. Sound management recommendations can only be based on reliable scientific research.

Procedures:

The present complementary rotation grazing system has been in place at the ranch headquarters of the Dickinson Experiment Station since 1983. It consists of a crested wheatgrass (*Agropyron desertorum*) pasture for spring grazing and an altai wildrye (*Elymus angustus*) pasture for fall and early winter grazing. Native range has been grazed during the summer and managed with a three pasture, twice over rotation system.

The intended purpose of the trial is to maximize herbage and livestock production for a cow-calf operation, lengthen the grazing season in the spring and fall, improve range condition of native range, and reduce total acreage required to carry a cow and calf. The intention is to accomplish these goals with a low number of pastures with few rotation times and be flexible enough to be adapted by a wide range of livestock operations. This type of grazing system should improve operation efficiency, reduce costs and decrease labor per unit of production, and increase saleable production per acre.

Data collected on the pastures in this study are above ground herbage production, plant species composition, leaf height measurements and phenological phases of eight major graminoid species, and animal weight performance. Commercial crossbred cattle are used in this trial.

Results and Discussion:

Condition of the pastures has improved since the beginning of this study. Plant species composition (Table 1) has improved and herbage production (Table 2) has generally improved in relation to environmental conditions. Stocking rate (Table 3) has been increased annually as condition of the pastures improved.

Animal weight performance in the first four years of this study have been very good on crested wheatgrass grazed from early May to early June (Table 4). Average cow weight gains have been 3.06 lbs./day and 110.3 lbs./acre. Average calf weight gains have been 2.03 lbs./day and 74.2 lbs./acre.

Cows were generally in very good condition coming off the crested wheatgrass and going onto native range in early June. Cow average weight gains were 0.59 lbs./day and 7.4 lbs./acre on native range (Table 4). Cows on the three pasture, twice over rotation grazing system did not lose weight after July as previously experienced on pastures grazed season long (Manske et al. 1984). Loss of weight was delayed until late September or early October. In 1986, this loss of weight by the cows started earlier than previous years in September. Cows were left on the native range until mid October. Calves generally have not experienced any decrease in weight gains during the period that the cows experienced weight loss, except in 1986. Calf gains had a decrease in weight gains in late September. Calf average weight gains have been 2.12 lbs./day and 26.4 lbs./acre on this native range grazing system in the first four years of the study (Table 4).

Cows and calves were moved to an altai wildrye pasture in mid October. No problems in grazing altai wildrye have occurred during the early period of mid October to mid November. Early gains by cows on altai wildrye were high and considered to be, in part, compensatory after coming off the native range with a couple weeks of weight reduction. Average daily gain for cows has been 0.87 lbs./day for the period of mid October to mid November. Average calf gains were 1.50 lbs./day for the same period.

Problems have developed on altai wildrye during the grazing period after mid November. In 1984, calves were left with the cows until 3 December. The cows lost 1.67 lbs./day between mid November and weaning. After weaning, dry cows maintained their weight with a slight gain of 0.13 lbs./day until 31 December. Calf gain between mid November and 3 December was not very good at 0.84 lbs./day. As a result, it is recommended that calves be weaned before 15 November. In 1985, calves were weaned 12 November with the intent of leaving the dry cows on the altai wildrye as long as weather would permit. An early winter snow storm occurred in November and the cows were fed hay. The cows did not go out and graze the altai wildrye after this single feeding. They lost an average of 7.54 lbs./day from 12 November to 2 December. In 1986, the calves were weaned 10 November. The cows generally lost weight on altai wildrye from 17 October to 12 December. The cows gained weight from 12 December to 29 December while a protein supplement was provided.

Summary:

The management of this complementary rotation grazing system has been based on ecological principles that consider the physiological needs, weaknesses, and strengths of the dominant plant species. Consideration of the nutritional needs of the livestock have been incorporated. Season of use of each pasture type was limited to periods of grazing when the detrimental effects of grazing were minimized and the potential for improvement in animal weight performance was maximized to near potential. Effort has been made to limit the number of pastures and rotation times to the minimum. One pasture of crested wheatgrass was used for spring grazing. A second pasture may be necessary to move the starting date earlier. The native range was managed with three pastures, each grazed two times during the grazing season. One pasture of altai wildrye was used in this system for fall and early winter grazing. The grazing season has been lengthened from the traditional 6 months to 7.1 months. This system has the potential to lengthen the grazing season to 8.4 months with additional research. The acreage required to carry a cow and calf was reduced from 24.4 acres for 6 months to 11.6 acres for 7.1 months.

By using a complementary rotation grazing system similar to the one at the Dickinson Experiment Station, livestock producers have the potential to: lengthen the grazing season, reduce the acreage required to feed a cow and calf, and increase the amount of saleable beef produced from each livestock unit.
